Efficient algorithms to perform linear algebra operations on 3D arrays in vector languages

François Cuvelier

2018/05/31

Abstract

In a few number of applications, a need arises to do some usual linear algebra operations on a very large number of very small matrices of the same size, referred in this report by 3D-array. These operations could be as simple as sum or products, or more complex like computation of determinants, factorizing, solving, ... The aim of this report is to describe some vectorized algorithms for each one of these operations and to give efficiency measures. For example, computing the LU decomposition with partial pivoting of one million of 8-by-8 matrices on our reference computer is performed in 3.1 seconds with Matlab, 5.6 seconds with Octave and 9.7 seconds with Python.

In this report we describe vectorized algorithms allowing some operations on a very large number of matrices of the same very small dimension: determinants, Cholesky or LU decomposition, solving ... These algorithms can be transposed in vectorized languages such as Matlab/Octave, Python, Scilab, Julia, ... provided that they contain 3D-arrays (or multidimensionnal arrays). The set of matrices is stored on a \( N \)-by-\( m \)-by-\( n \) 3D-array array where \( N \) is the number of matrices of dimensions \( m \)-by-\( n \). In some vectorized languages, parts of these operations could be already implemented. They are referenced as broadcasting under Octave and Python, and as expanding arrays with compatible sizes under Matlab:

Matlab: [Link to Matlab documentation on broadcasting](https://fr.mathworks.com/help/matlab/matlab_prog/compatible-array-sizes-for-basic-operations.html)

Octave: [Link to Octave documentation on broadcasting](https://www.gnu.org/software/octave/doc/v4.4.0/Broadcasting.html)

Python: [Link to Python documentation on broadcasting](https://docs.scipy.org/doc/numpy/user/basics.broadcasting.html)

In a first section, notations and definitions are given and some linear algebra operations such as linear combinations, matricial products, determinants, solving linear systems are extended to 3D-arrays. In the second section we introduce some algorithmic tools and functions used in this report. We use them on basic linear algebra operations on 3D-arrays to obtain various algorithms on linear combinations and matricial products. We also give very simple algorithms for elements by elements operations. Thereafter algorithms solving triangular upper systems and triangular lower systems stored in a 3D-array are described and their runtimes are computed for the three vectorized languages Matlab, Octave and Python. In section 4 various vectorized algorithms are detailed to obtain factorizations of all the matrices in a 3D-array: Cholesky factorization and LU factorization with partial pivoting are study. Then in section 5 some vectorized algorithms for solving linear systems stored in 3D-arrays are proposed. Finally, computation of determinants is study by using Laplace expansion or factorizations.

In all this report, for each kind of algorithms runtimes\(^1\) is given for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Some usual operations provided with vectorized languages are detailed in Appendix A.

All the source codes used can be

1. Notations and definitions

Some typographic conventions are used:

- Z, N, R, C are respectively the set of integers, positive integers, reals and complex numbers. \( K \) is either \( R \) or \( C \).
- All vectors or 1D-arrays are represented in bold: \( v \in \mathbb{R}^n \) or \( X \) a 1D-array. The first alphabetic characters are \( aBcC \ldots \)

---

\(^1\)Computer with 1 Intel(R) Core(TM) i9-7940X CPU @ 3.10GHz processor (14 cores and 2 threads by core), 62GB of available RAM and Ubuntu 17.10 as operating system.
• All matrices or 2D-arrays are represented with the blackboard font as: \( \mathbb{M} \in \mathcal{M}_{m,n}(\mathbb{K}) \) or \( \mathbb{b} \) a \( m \times n \) 2D-array. The first alphabetic characters are \( \mathbb{aAbBcC} \)....

• All arrays of matrices or 3D-arrays are represented with the bold blackboard font as: \( \mathbb{M} \in (\mathcal{M}_{m,n}(\mathbb{K}))^N \) or \( \mathbb{b} \) a \( m \times n \times p \) 3D-array. The first alphabetic characters are \( \mathbb{aAbBcC} \)....

We now introduce some notations. Let \( \mathbb{A} = (A_1, \ldots, A_N) \in (\mathcal{M}_{m,n}(\mathbb{K}))^N \) where \( N \geq m, n \). We identify \( \mathbb{A} \) with a \( N \times m \times n \) 3D-array such that

\[
A(k, :, :) = A_k, \quad \forall k \in [1, N].
\]

Thereafter, we said that a 3D-array \( \mathbb{A} \in (\mathcal{M}_{m,n}(\mathbb{K}))^N \) has a matricial property if all the \( A_k \) matrices have this property. For example, \( \mathbb{A} \) is a symmetrical 3D-array if all its matrices are symmetrical.

In the following we described element by element operations on 3D-arrays.

### 1.1 Element by element operations

Some simple vectorized element by element operations (addition, substraction, multiplication, ...) are often already coded with multidimensional arrays. For example the addition of two multidimensional arrays with same size or the addition of a multidimensional array with a scalar could be done with the `+` operator with Matlab, Octave, Python, Scilab, ... Nevertheless, for our purpose we also want to be able to add a 3D-array with a 1D-array or with a matrix as described in the following subsection respectively in \( [5] \) and \( [3] \). These operations are not always available or are not directly usable on vectorized languages. For example with Matlab (\( \geq R2016b \)) or Octave

- to add a \( N \times d \times d \) 3D-array with a \( N \times 1 \) 1D-array (see \( [5] \)) one can do
  \[
  \text{randn}(N,d,d) + \text{randn}(N,1)
  \]

- to add a \( N \times d \times d \) 3D-array with a \( d \times d \) 2D-array (see \( [3] \)) one cannot do \( \text{randn}(N,d,d) + \text{randn}(d,d) \). The correct command is
  \[
  \text{randn}(N,d,d) + \text{randn}(1,d,d) \text{ or } \text{randn}(N,d,d) + \text{reshape(\text{randn}(d,d),[1,d,d])}
  \]

We want to define the element by element operation

\[
C \leftarrow A \odot B
\]

where \( A \) and/or \( B \) are 3D-arrays, \( \odot \) is a vectorized element by element binary operator associated with the usual scalar operator \( \odot \). In Table\( [4] \) some examples of operators are provided.

Let \( \mathbb{A} \in (\mathcal{M}_{m,n}(\mathbb{K}))^N \), We define four kinds of such operations:

1. Let \( \mathbb{B} \in (\mathcal{M}_{m,n}(\mathbb{K}))^N \), we set

\[
\mathbb{A} \odot \mathbb{B} \overset{\text{def}}{=} \mathbb{C} \in (\mathcal{M}_{m,n}(\mathbb{K}))^N
\]

where \( \forall k \in [1, N] \)

\[
\forall i \in [1, m], \forall j \in [1, n], \quad C_k(i, j) = A_k(i, j) \odot B_k(i, j).
\]

2. Let \( B \in \mathcal{M}_{m,n}(K) \), we set

\[
\mathbf{A} \diamond \mathbf{B} \overset{\text{def}}{=} \mathbf{C} \in (\mathcal{M}_{m,n}(K))^N
\]

\[
\mathbf{B} \diamond \mathbf{A} \overset{\text{def}}{=} \mathbf{D} \in (\mathcal{M}_{m,n}(K))^N
\]

where \( \forall k \in [1, N] \)

\[
\forall i \in [1, m], \forall j \in [1, n], \quad \begin{cases} C_k(i, j) = A_k(i, j) \diamond B(i, j), \\ D_k(i, j) = B(i, j) \diamond A_k(i, j). \end{cases}
\]

3. Let \( B \in K^N \), we set

\[
\mathbf{A} \diamond B \overset{\text{def}}{=} \mathbf{C} \in (\mathcal{M}_{m,n}(K))^N
\]

\[
B \diamond \mathbf{A} \overset{\text{def}}{=} \mathbf{D} \in (\mathcal{M}_{m,n}(K))^N
\]

where \( \forall k \in [1, N] \)

\[
\forall i \in [1, m], \forall j \in [1, n], \quad \begin{cases} C_k(i, j) = A_k(i, j) \diamond B(k), \\ D_k(i, j) = B(k) \diamond A_k(i, j). \end{cases}
\]

4. Let \( B \in K \), we set

\[
\mathbf{A} \diamond B \overset{\text{def}}{=} \mathbf{C} \in (\mathcal{M}_{m,n}(K))^N
\]

\[
B \diamond \mathbf{A} \overset{\text{def}}{=} \mathbf{D} \in (\mathcal{M}_{m,n}(K))^N
\]

where \( \forall k \in [1, N] \)

\[
\forall i \in [1, m], \forall j \in [1, n], \quad \begin{cases} C_k(i, j) = A_k(i, j) \diamond B, \\ D_k(i, j) = B \diamond A_k(i, j). \end{cases}
\]

1.2 Linear Algebra

1.2.1 Determinants

Let \( \mathbf{A} \in (\mathcal{M}_{m,n}(K))^N \). The determinant of \( \mathbf{A} \), denoted by \( \det \mathbf{A} \), is the vector \( \mathbf{D} \in K^N \) such that

\[
D(k) = \det(k, \cdot, \cdot), \quad \forall k \in [1, N].
\]
1.2.2 Matricial products

Let $X$ be in $(\mathcal{M}_{m,n}(K))^N$ or $\mathcal{M}_{m,n}(K)$, and $Y$ be in $(\mathcal{M}_{n,p}(K))^N$ or $\mathcal{M}_{n,p}(K)$, where either one of the two is a 3D-array. We extend the matricial product to 3D-arrays

$$X \ast Y = Z \in (\mathcal{M}_{m,p}(K))^N$$

(10)

where $\forall k \in [1, N]$

$$Z(k, ::, ::) = \begin{cases} X(k, ::, ::) \ast Y(k, ::, ::), & \text{if } X \in (\mathcal{M}_{m,n}(K))^N \text{ and } Y \in (\mathcal{M}_{n,p}(K))^N, \\ X(k, ::, ::) \ast Y, & \text{if } X \in (\mathcal{M}_{m,n}(K)^N) \text{ and } Y \in M_{n,p}(K), \\ X \ast Y(k, ::, ::), & \text{if } X \in \mathcal{M}_{m,n}(K) \text{ and } Y \in (\mathcal{M}_{n,p}(K))^N. \end{cases}$$

In these formulas, the operator $\ast$ denotes the matricial product between a $m$-by-$n$ matrix and a $n$-by-$p$ matrix.

1.2.3 Linear systems

Let $A \in (\mathcal{M}_{m,n}(K))^N$ and let $B$ be in $(\mathcal{M}_{n,p}(K))^N$ or in $M_{n,p}(K)$. We want to find $X \in (\mathcal{M}_{m,p}(K))^N$ such that

$$A \ast X = B$$

(11)

that is to say, for all $k \in [1, N]$, find $X_k \in \mathcal{M}_{d,n}(K)$ solution of the linear system

$$A_k \ast X_k = \begin{cases} B_k, & \text{if } B \in (\mathcal{M}_{n,p}(K))^N, \\ B, & \text{if } B \in M_{n,p}(K). \end{cases}$$

1.2.4 Positive Cholesky factorization

Let $A \in (\mathcal{M}_{d,d}(\mathbb{C}))^N$ be a hermitian positive definite 3D-array:

$$\forall k \in [1, N], \ A(k, ::, ::) = A_k \in \mathcal{M}_n(\mathbb{C}) \text{ is a hermitian positive definite matrix.}$$

The positive Cholesky factorization of $A$ is given by

$$A = LL^*$$

(12)

where $L \in (\mathcal{M}_{d,d}(\mathbb{C}))^N$ is lower triangular with real and positive diagonal entries (i.e. $\forall k \in [1, N]$, $L(k, ::, ::) = L_k \in \mathcal{M}_n(\mathbb{C})$ are lower triangular matrices with real and positive diagonal entries) The equation (12) can be equivalently written as

$$\forall k \in [1, N], A_k = L_k L_k^*.$$

1.2.5 LU factorization with partial pivoting

Let $A \in (\mathcal{M}_{d,d}(K))^N$. The LU factorization with partial pivoting of $A$ is given by

$$PA = LU$$

(13)

where $L$, $U$ and $P$ are in $(\mathcal{M}_{d,d}(K))^N$ and

- $L$ is a lower triangular 3D-array with unit diagonal, i.e. $\forall k \in [1, N]$, $L(k, ::, ::) = L_k \in \mathcal{M}_d(K)$ are lower triangular matrices with unit diagonal.
• $U$ is a upper triangular 3D-array, 
  \[ U(k, :, :) = U_k \in \mathcal{M}_d(K) \] are upper triangular matrices, 

• $P$ is a permutation 3D-array, 
  \[ P(k, :, :) = P_k \in \mathcal{M}_d(K) \] are permutation matrices, 

So we have, for all $k \in [1, N]$, 

\[ P_k A_k = L_k U_k \]

## 2 Basic Linear Algebra Vectorized operations

To introduce some algorithmic functions we present, in the next subsection, various versions of the linear combinations function called $\text{AXpY}$:

- $\text{AXpY}_\text{Cpt}$, component by component computation (3 loops)
- $\text{AXpY}_\text{Mat}$, using 2D-array or matricial operations (1 loop over number of matrices),
- $\text{AXpY}_\text{Vec}$, vectorized algorithm (2 loops over rows and columns of the matrices),
- $\text{AXpY}_\text{Cvt}$, using operations between 3D-arrays (no loop)

Thereafter same versions are written for for element by elements functions. At last, theses versions are provided for the matricial product function called $\text{mtimes}$.

### 2.1 Linear Combinations

Let $X$ and $Y$ be in $(\mathcal{M}_{m,n}(K))^N$, $\mathcal{M}_{m,n}(K)$, $K^N$ or $K$ where either one of the two is in $(\mathcal{M}_{m,n}(K))^N$. Let $\alpha$ and $\beta$ in $K$, we can compute

\[ Z = \alpha X + \beta Y \in (\mathcal{M}_{m,n}(K))^N \] 

by using one of the formulas (2) to (8). In Python with Numpy, Matlab (>=2016b) and Octave (>= 4.0.3?) such operations are partially supported. Let $X \in (\mathcal{M}_{m,n}(K))^N$, $Y \in \mathcal{M}_{m,n}(K)$ and $Z \in K^N$, we want to compute

\[ \begin{align*} 
C &= 7 \ast X - 5 \ast Y \quad \text{and} \quad D = 3 \ast X + 4 \ast Z 
\end{align*} \]

- with Matlab (>=2016b) and Octave, one has to expand $Y$ to a 1-by-$m$-by-$n$ 3D-array to fit broadcasting rules by using $\text{reshape}$ function:

```matlab
N=10^5;m=3;n=2;
X=randn(N,m,n);Y=randn(m,n);Z=randn(N,1);
C=7*X-5*reshape(Y,[1,m,n]);
D=3*X+4*Z;
```
with Matlab (<2016b), one has to expand $Y$ to a $N$-by-$m$-by-$n$ 3D-array by using *reshape* and *repmat* functions:

```matlab
N=10^5; m=3; n=2;
X=randn(N,m,n); Y=randn(m,n); Z=randn(N,1);
C=7*X-5*repmat(reshape(Y,[1,m,n]),N,1,1);
D=3*X+4*repmat(Z,1,m,n);
```

with Python, one has to expand $Z$ to a $N$-by-$1$-by-$1$ 3D-array to fit broadcasting rules by using *reshape* function:

```python
import numpy as np
N=10^5; m=3; n=2
X=np.random.randn(N,m,n)
Y=np.random.randn(m,n)
Z=np.random.randn(N)
C=7*X-5*Y
D=3*X+4*np.reshape(Z,[N,1,1])
```

To introduce the functions *getCpt*, *getMat*, *getVec* and *to3Darray* we now present some algorithms implementing [14] without using broadcasting.

A very basic function called *AXpBY_Cpt* using three loops is given in Algorithm 1 where computation of $Z$ is done component by component.

```plaintext
Algorithm 1 Function *AXpBY_Cpt*, returns linear combination $\alpha X + \beta Y$ by using component by component computation.

Function $Z \leftarrow \text{AXpBY_Cpt}(\alpha, X, \beta, Y)$
for $k \leftarrow 1$ to $N$ do
    for $i \leftarrow 1$ to $m$ do
        for $j \leftarrow 1$ to $n$ do
            $Z(k,i,j) \leftarrow \alpha \cdot \text{getCpt}(X,k,i,j) + \beta \cdot \text{getCpt}(Y,k,i,j)$
        end for
    end for
end for
```

We present in Algorithm 2 another version where linear combination of two multidimensional arrays with same size supposed to be in our vectorized language: this version is quite efficient but memory consuming.

```plaintext
Algorithm 2 Function *getCpt*, returns component $(i,j)$ of the $k$-th matrix of $X$.

Function $s \leftarrow \text{getCpt}(X,k,i,j)$
if $X \in \mathbb{K}^N$ then
    $s \leftarrow X$
else if $X \in \mathbb{K}^n$ then
    $s \leftarrow X(k)$
else if $X \in \mathbb{M}_{m,n}(\mathbb{K})$ then
    $s \leftarrow X(i,j)$
else
    $s \leftarrow X(k,i,j)$
end if
```

8
An other way is to use operations defined on 2D-array (or matrices) which are supposed to be defined in the vectorized language: that’s give the Algorithm 5

As \( N \) supposed to be very large in front of \( n \) and \( m \), the Algorithm 5 is not efficient: the main loop to suppress is the loop over \( N \). This is the object of the Algorithm 7
In Table 2, the computation time in second of these four functions under Matlab, Octave and Python are given when the input arrays are $X \in (\mathcal{M}_{3,3}(K))^N$ and $Y \in \mathcal{M}_{3,3}(\mathbb{R})$ and with a number $N$ up to $10^5$ for the slower function $\text{AXpbY}_\text{Cpt}$ and up to $10^6$ for the others. As expected the two functions $\text{AXpbY}_\text{Vec}$ and $\text{AXpbY}_\text{Cvt}$ are the fastest. Indeed when broadcasting is available in vector language these two functions are less efficient than the broadcasting one given in Table 2 by the function $\text{AXpbY}_\text{Nat}$. In Table 3 and 4 computation time in second of the $\text{AXpbY}_\text{Nat}$ function and for $N$ up to $10^5$ are given when the input array $X \in (\mathcal{M}_{3,3}(K))^N$ and the input array $Y$ respectively in $\mathcal{M}_{3,3}(\mathbb{R})$ and in $(\mathcal{M}_{3,3}(K))^N$. In Tables 5 to 8 effects of multi-threading with Matlab are provided respectively for the functions $\text{AXpbY}_\text{Mat}$, $\text{AXpbY}_\text{Vec}$, $\text{AXpbY}_\text{Cvt}$ and $\text{AXpbY}_\text{Nat}$.

Table 8: Function $\text{AXbyY}_\text{MAT}$ with $X \in (\mathcal{M}_{3,3}(\mathbb{K}))^N$ and $Y \in \mathcal{M}_{3,3}(\mathbb{R})$ under Matlab 2018a: effects of multithreading on cpu times

2.2 Element by element operations

From the four Algorithms 1, 3, 5 and 7 and by using notations and definitions of section 1.1 we deduce four generic functions which computes $X \otimes Y$. There are given in Algorithms 9 to 11.

Algorithm 9 Function $\text{AXbyY}_Cvt$ returns element by element operation $X \otimes Y$. There $f$ is the function $f : (x, y) \in \mathbb{K}^2 \rightarrow x \otimes y$

```
\begin{algorithm}
\textbf{for} $k \leftarrow 1 \text{ to } N \text{ do}$
\textbf{for} $i \leftarrow 1 \text{ to } m \text{ do}$
\textbf{for} $j \leftarrow 1 \text{ to } n \text{ do}$
\textbf{end for}
\textbf{end for}
\textbf{end for}
\end{algorithm}
```

Algorithm 10 Function $\text{AXbyY}_\text{MAT}$ returns element by element operation $X \otimes Y$ by using function $f : (A, B) \rightarrow A \otimes B$ where $A$ and $B$ are in $\mathbb{M}_{m,n}(\mathbb{K})$ or in $\mathbb{R}$.

```
\begin{algorithm}
\textbf{Function} $\text{C} \leftarrow \text{AXbyY}_\text{MAT}(X, Y, f)$
\textbf{for} $k \leftarrow 1 \text{ to } N \text{ do}$
$A \leftarrow \text{getMat}(X, k)$
$B \leftarrow \text{getMat}(Y, k)$
$\text{C}(k, :, :) \leftarrow f(A, B)$
\textbf{end for}
\end{algorithm}
```

Algorithm 11 Function $\text{AXbyY}_\text{VEC}$ returns element by element operation $X \otimes Y$ by using function $f : (A, B) \rightarrow A \otimes B$ where $A$ and $B$ are in $\mathbb{K}^2$. Elements

```
\begin{algorithm}
\textbf{Function} $\text{C} \leftarrow \text{AXbyY}_\text{VEC}(X, Y, f)$
\textbf{for} $j \leftarrow 1 \text{ to } m \text{ do}$
\textbf{end for}
\end{algorithm}
```

Algorithm 12 Function $\text{AXbyY}_\text{Cvt}$ returns element by element operation $X \otimes Y$ by converting arrays to 3D-arrays. Here $f$ is the function $f : (A, B) \rightarrow A \otimes B$ where $A$ and $B$ are in $\mathbb{M}_{m,n}(\mathbb{K})^N$

```
\begin{algorithm}
\textbf{Function} $\text{Z} \leftarrow \text{AXbyY}_\text{Cvt}(X, Y, f)$
\textbf{for} $j \leftarrow 1 \text{ to } m \text{ do}$
\end{algorithm}
```

Thereafter, writing functions for a specific element by element operator is easy. For example, the corresponding functions for element by element multiplication.
In Table 9, the computation time in seconds for these four functions using Matlab, Octave and Python are given when the input arrays are $X \in (M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$. For the `times_Cpt` function, the $N$ values are up to $10^5$ and for the other functions up to $10^6$. As expected, the two functions `times_Vec` and `times_Cpt` are the fastest. Indeed, when broadcasting is available in vector language, these two functions are less efficient than the broadcasting one given in Table 9 by the function `times_Nat`.

(e) Function `times_Nat`

Table 9: Computational times in seconds of `times` functions with $X \in (M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
2.3 Matricial products

In section 1.2.2 matricial product with 3D-arrays is defined and the corresponding function is called \texttt{mtimes}.

From the three Algorithms 1, 7 and 5 we deduce three functions which computes (10). They are given respectively in Algorithms 17, 18 and 19.

\begin{algorithm}
\caption{Function \texttt{mtimes\_Cpt}, returns matricial products $X \ast Y$ where $X$ or/and $Y$ are 3D-arrays.}
\begin{algorithmic}
\Function {\texttt{mtimes\_Cpt}}{$X, Y$}
\For{$k \leftarrow 1$ to $N$}
\For{$i \leftarrow 1$ to $m$}
\For{$j \leftarrow 1$ to $p$}
\State $S \leftarrow 0$
\For{$l \leftarrow 1$ to $n$}
\State $S \leftarrow S + \text{getCpt}^p(X, k, i, l) \ast \text{getCpt}^p(Y, k, l, j)$
\EndFor
\EndFor
\State $C(k, i, j) \leftarrow S$
\EndFor
\EndFor
\EndFunction
\end{algorithmic}
\end{algorithm}

\begin{algorithm}
\caption{Function \texttt{mtimes\_Vec}, returns matricial products $X \ast Y$ where $X$ or/and $Y$ are 3D-arrays.}
\begin{algorithmic}
\Function {\texttt{mtimes\_Vec}}{$X, Y$}
\For{$i \leftarrow 1$ to $m$}
\For{$j \leftarrow 1$ to $p$}
\State $S \leftarrow \text{zeros}(N, 1)$
\For{$l \leftarrow 1$ to $n$}
\State $S \leftarrow S + \text{getVec}^p(X, i, l) \ast \text{getVec}^p(Y, l, j)$
\EndFor
\State $C(:, i, j) \leftarrow S$
\EndFor
\EndFor
\EndFunction
\end{algorithmic}
\end{algorithm}

\begin{algorithm}
\caption{Function \texttt{mtimes\_Mat}, returns matricial products $X \ast Y$ where $X$ or/and $Y$ are 3D-arrays.}
\begin{algorithmic}
\Function {\texttt{mtimes\_Mat}}{$X, Y$}
\For{$k \leftarrow 1$ to $N$}
\State $C(k, :, :) \leftarrow \text{getMat}^p(X, k) \ast \text{getMat}^p(Y, k)$
\EndFor
\EndFunction
\end{algorithmic}
\end{algorithm}

In Python, the \texttt{matmul} function of the Numpy package (\geq 1.10.0) directly do these kind of operations and it’s also implements the semantics of the $\otimes$ operator introduced in Python 3.5. In Matlab 2018a and Octave 4.4.0 no function is available to perform such operations.

In Table 10 computational time in second of these three functions under Matlab, Octave and Python are given when the input arrays are $X \in (\mathcal{M}_{3,3}(\mathbb{R}))^N$ and $Y \in \mathcal{M}_{3,3}(\mathbb{R})$. For the \texttt{mtimes\_Cpt} function the $N$ value is up to $10^5$ and for the other functions up to $10^6$. As expected the function \texttt{mtimes\_Vec} is the fastest.

In Table 11 computational time in second of the \texttt{mtimes\_Vec} function for the same input datas is given for $N$ up to $10^7$. To see effect of (automatic) multithreading under Matlab, we also add computational times of the function when using only one thread. One can also compare with the native function in Python which uses the \texttt{matmul} function of the Numpy package.

In Table 12 computational time of the same functions are given but for $X$ and $Y$ in $(\mathcal{M}_{3,3}(\mathbb{R}))^N$.

Table 10: Computational times in seconds of mtimes functions with $X \in (M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Table 11: Computational times in seconds of mtimes_VEC functions with $X$ in $(M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. Matlab(*) refers to Matlab without multi-threadings and Python(Nat) to Numpy matmul function.

Table 12: Computational times in seconds of mtimes_VEC functions with $X$ and $Y$ in $(M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. Matlab(*) refers to Matlab without multi-threadings and Python(Nat) to Numpy matmul function.
Figure 1: Computational times in seconds of the \texttt{mtimes\_Vec} function with $X$ and $Y$ both in $(M_{d,d}(K))^N$, $N = 10^6$ and $d \in [2, 10]$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Figure 2: Computational times in seconds of the \texttt{mtimes\_Vec} function with $X \in (M_{d,d}(K))^N$, $Y \in M_{d,d}(R)$, $N = 10^6$ and $d \in [2, 10]$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
3 Linear solver for particular 3D-arrays

In this section we suppose that $A \in (M_{n,n}(K))^N$ is regular, i.e. all the $A_k$ matrices are regular. Let $B$ be in $(M_{p,p}(K))^N$ or in $M_{n,p}(K)$. As defined in section 1.2.3 we want to find $X \in (M_{n,p}(K))^N$ such that

$$A \cdot X = B$$

In this section we give the \texttt{LinsolveDiag} function and various versions of the \texttt{LinsolveTriL} and \texttt{LinsolveTriU} functions which solve linear systems respectively with $A$ diagonal, lower triangular and upper triangular.

3.1 Diagonal matrices

Firstly we recall some very simple results. Let $D \in M_{d,d}(K)$ be a regular diagonal matrix. If $b \in K^d$ then the solution $x \in K^d$ of the linear system $DX = b$ is given by

$$x_i = b_i/D_{i,i}, \ \forall i \in [1,d].$$

If $B \in M_{d,n}(K)$ then the solution $X \in M_{d,n}(K)$ of $DX = B$ is given by

$$X_{i,l} = B_{i,l}/D_{i,i}, \ \forall i \in [1,d], \ \forall l \in [1,m].$$

Now, one can easily extend these results to regular diagonal 3D-array. Let $A \in (M_{d,d}(K))^N$ be a regular diagonal 3D-array, i.e. each $A_k \equiv A(k, :, :)$ is a regular diagonal matrix, and so $\forall k \in [1,N]$, $\forall (i, j) \in [1,d]^2$

$$A_k(i, j) = 0, \ \text{if } i \neq j$$

$$A_k(i, i) \neq 0.$$

Let $B \in (M_{d,n}(K))^N$ or $B \in M_{d,n}(K)$, we want to solve the linear systems

$$AX = B$$

as described in section 1.2.3. If $B \in M_{d,n}(K)$ then we have

$$X(k, i, l) = B(i, l)/A(k, i, i), \ \forall i \in [1,d], \ \forall l \in [1,n], \ \forall k \in [1,N]$$

and if $B \in (M_{n,m}(K))^N$ we obtain

$$X(k, i, l) = B(k, i, l)/A(k, i, i), \ \forall i \in [1,d], \ \forall l \in [1,n], \ \forall k \in [1,N].$$

By using the function \texttt{getVec} described in Algorithm 8 we obtain the vectorized Algorithm 20.
Algorithm 20 Function LINSOLVE_DIAG, solves diagonal linear system $AX = B$.

Input $\mathbf{A}$ : in $(\mathcal{M}_{d,d}(K))^N$
$\mathbf{B}$ : in $(\mathcal{M}_{d,n}(K))^N$, or in $\mathcal{M}_{d,n}(K)$

Output $\mathbf{X}$ : in $(\mathcal{M}_{d,n}(K))^N$

Function $\mathbf{X} \leftarrow$ LINSOLVE_DIAG ($\mathbf{A}, \mathbf{B}$)
for $l \leftarrow 1$ to $m$ do
    for $i \leftarrow 1$ to $d$ do
        $\mathbf{X}(:,i,l) \leftarrow \text{getVec} (\mathbf{B},i,l) / \mathbf{A}(i,i)$
    end for
end for

3.2 Lower triangular matrices

Firstly we recall some classical formulas. Let $\mathbf{A} \in \mathcal{M}_{d,d}(K)$ be a regular lower triangular matrix. If $\mathbf{B} \in \mathcal{M}_{d,n}(K)$ then the solution $\mathbf{X} \in \mathcal{M}_{d,n}(K)$ of

$$AX = B$$

(15)
can be computed column by column. For each column $l$, we successively compute $\mathbf{X}_{1,l}, \mathbf{X}_{2,l}, \ldots, \mathbf{X}_{d,l}$ by using formula

$$\mathbf{X}_{i,l} = (\mathbf{E}_{i,l} - \sum_{j=1}^{i-1} \mathbf{A}_{i,j} \mathbf{X}_{j,l}) / \mathbf{A}_{i,i}, \quad \forall i \in [1,d], \quad \forall l \in [1,n].$$

(16)
or in a more compact form we successively compute $\mathbf{X}_{i,:}, \mathbf{X}_{2,:}, \ldots, \mathbf{X}_{d,:}$, by using formula

$$\mathbf{X}_{i,:} = (\mathbf{E}_{i,:} - \mathbf{A}_{i,1:i-1} \mathbf{X}_{1,i-1,:}) / \mathbf{A}_{i,i}, \quad \forall i \in [1,d].$$

(17)
A such operation is given by the LINSOLVE_TRI function described in Algorithm 21.

Now, one can extend these results to regular lower triangular 3D-array. Let $\mathbf{A} \in (\mathcal{M}_{d,d}(K))^N$ be a regular lower triangular 3D-array, i.e. each $\mathbf{A}_k$ defined $\mathbf{A}(k,:,:)$ is a regular lower triangular matrix, and so $\forall k \in [1,N], \forall (i,j) \in [1,d]^2$

$$\mathbf{A}_k(i,j) = 0, \quad \text{if } i < j$$

$$\mathbf{A}_k(i,i) \neq 0.$$

By using LINSOLVE_TRI and GETMAT functions respectively described in Algorithm 21 and Algorithm 6, we easily obtain the non-vectorized function LINSOLVE_TRI_MAT written in Algorithm 22. In Algorithm 23 an other code is presented without using function LINSOLVE_TRI_MAT. This code uses GET_CPT function given in Algorithm 2 and by permuting the main loop in $k$ with the two others in $l$ and $i$, we deduce the vectorized function LINSOLVE_TRI_VEC given in Algorithm 24.
In Table 13 the computation time in second for the three functions $\text{Linsol\_veTriL\_Cpt}$, $\text{Linsol\_veTriL\_Mat}$ and $\text{Linsol\_veTriL\_Vec}$ under Matlab, Octave and Python are given with $\mathbf{A} \in (\mathcal{M}_{d,3}(K))^N$ and $\mathbf{B} \in (\mathcal{M}_{d,1}(K))^N$. As expected the function $\text{Linsol\_veTriL\_Vec}$ is the fastest. In Table 14 the computation time in second of the $\text{Linsol\_veTriL\_Vec}$ function is given for $N$ values up to $10^6$. Finally, we give in Figure 3 computational times in second of the $\text{Linsol\_veTriL\_Vec}$ with $\mathbf{A} \in (\mathcal{M}_{d,d}(K))^N$, $\mathbf{B} \in (\mathcal{M}_{d,1}(K))^N$, for $N = 10^6$ and $d \in [2, 10]$.  

### 3.3 Upper triangular matrices

Firstly we recall some classical formulas. Let $\mathbf{A} \in \mathcal{M}_{d,d}(K)$ be a regular upper triangular matrix. If $\mathbf{B} \in \mathcal{M}_{d,n}(K)$ then the solution $\mathbf{X} \in \mathcal{M}_{d,n}(K)$ of

$$\mathbf{AX} = \mathbf{B}$$

can be computed column by column. For each column $l$, we successively compute $X_{d,l}, X_{d-1,l}, \ldots, X_{1,l}$ by using formula

$$X_{i,l} = (B_{i,l} - \sum_{j=i+1}^{d} A_{i,j} X_{j,l}) / A_{i,i}, \quad \forall i \in [1, d], \forall l \in [1, n].$$

or in a more compact form we successively compute $X_{d,:}, X_{d-1,:), \ldots, X_{1,:}$ by using formula

$$X_{i,:} = (B_{i,:) - A_{i,i+1:d, :} X_{i+1:d,:}) / A_{i,i}, \quad \forall i \in [1, d].$$

#### Algorithm 21 Function $\text{Linsol\_veTriL\_Cpt}$, solves equation $\mathbf{AX} = \mathbf{B}$ where $\mathbf{A}$ is a regular lower triangular matrix.

**Input**
- $\mathbf{A}$ : in $\mathcal{M}_{d,d}(K)$
- $\mathbf{B}$ : in $\mathcal{M}_{d,n}(K)$

**Output**
- $\mathbf{X}$ : in $\mathcal{M}_{d,n}(K)$

```plaintext
1: Function $\mathbf{X} = \text{Linsol\_veTriL\_Cpt} (\mathbf{A}, \mathbf{B})$
2: for $l \leftarrow 1$ to $n$ do
3: for $i \leftarrow 1$ to $d$ do
4: $S \leftarrow 0$
5: for $j \leftarrow 1$ to $i-1$ do
6: $S \leftarrow S + A_{i,j} X_{j,l}$
7: end for
8: $X_{i,l} \leftarrow (B_{i,l} - S) / A_{i,i}$
9: end for
10: end for
11: end Function
```

#### Algorithm 22 Function $\text{Linsol\_veTriL\_Mat}$, solves equation $\mathbf{AX} = \mathbf{B}$ where $\mathbf{A}$ is a regular lower triangular matrix (not vectorized).

**Input**
- $\mathbf{A}$ : in $(\mathcal{M}_{d,d}(K))^N$
- $\mathbf{B}$ : in $(\mathcal{M}_{d,n}(K))^N$, or in $\mathcal{M}_{d,n}(K)$

**Output**
- $\mathbf{X}$ : in $(\mathcal{M}_{d,n}(K))^N$

```plaintext
1: Function $\mathbf{X} = \text{Linsol\_veTriL\_Mat} (\mathbf{A}, \mathbf{B})$
2: for $k \leftarrow 1$ to $N$ do
3: for $i \leftarrow 1$ to $d$ do
4: $S \leftarrow 0$
5: for $j \leftarrow 1$ to $i-1$ do
6: $S \leftarrow S + A_{i,j} X_{j,k}$
7: end for
8: $X_{i,k} \leftarrow (B_{i,k} - S) / A_{i,i}$
9: end for
10: end for
11: end Function
```

#### Algorithm 23 Function $\text{Linsol\_veTriL\_Vec}$, solves equation $\mathbf{AX} = \mathbf{B}$ where $\mathbf{A}$ is a regular lower triangular matrix (vectorized).

**Input**
- $\mathbf{A}$ : in $(\mathcal{M}_{d,d}(K))^N$
- $\mathbf{B}$ : in $(\mathcal{M}_{d,n}(K))^N$, or in $\mathcal{M}_{d,n}(K)$

**Output**
- $\mathbf{X}$ : in $(\mathcal{M}_{d,n}(K))^N$

```plaintext
1: Function $\mathbf{X} = \text{Linsol\_veTriL\_Vec} (\mathbf{A}, \mathbf{B})$
2: for $l \leftarrow 1$ to $n$ do
3: for $i \leftarrow 1$ to $d$ do
4: $S \leftarrow 0$
5: for $j \leftarrow 1$ to $i-1$ do
6: $S \leftarrow S + A_{i,j} X_{j,l}$
7: end for
8: $X_{i,l} \leftarrow (B_{i,l} - S) / A_{i,i}$
9: end for
10: end for
11: end Function
```

Table 14: Computational times in seconds of the **LinsolveTril_Vec** function with $\mathbf{A} \in (\mathcal{M}_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
Figure 3: Computational times in seconds of the \texttt{LinsolveTriL\_Vec} function with $A \in (\mathcal{M}_{d,d}(K))^N$, $B \in (\mathcal{M}_{d,1}(K))^N$, $N = 10^6$ and $d \in [2, 10]$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
A such operation is given by the \texttt{LinsolveTriU} function described in Algorithm 25.

Now, one can extend these results to \textbf{regular upper triangular} 3D-array. Let $\mathbf{A} \in (\mathcal{M}_{d,d}(K))^N$ be a \textbf{regular upper triangular} 3D-array, i.e. each $\mathbf{A}_{k}^{dd} = \mathbf{A}(k,\cdot,\cdot)$ is a regular upper triangular, and so $\forall k \in [1,N], \forall (i,j) \in [1,d]^2$

\[
\mathbf{A}_k(i,j) = 0, \text{ if } i > j
\]

By using \texttt{LinsolveTriU} and \texttt{getMat} functions respectively described in Algorithm 25 and Algorithm 26 we easily obtain the non-vectorized function \texttt{LinsolveTriU\_Mat} written in Algorithm 26. In Algorithm 27 another code is presented without using function \texttt{LinsolveTriU\_Mat}. This code uses \texttt{getCpt} function given in Algorithm 25 and by permuting the main loop in $k$ with the two others in $l$ and $i$, we deduce the vectorized function \texttt{LinsolveTriU\_Vec} given in Algorithm 28.

In Table 15 the computation time in second for the three functions \texttt{LinsolveTriU\_Cpt}, \texttt{LinsolveTriU\_Mat} and \texttt{LinsolveTriU\_Vec} under Matlab, Octave and Python are given with $\mathbf{A} \in (\mathcal{M}_{d,d}(K))^N$ and $\mathbf{B} \in (\mathcal{M}_{d,1}(K))^N$. As expected the function \texttt{LinsolveTriU\_Vec} is the fastest. In Table 16 the computation time in second of the \texttt{LinsolveTriU\_Vec} function is given for $N$ values up to $10^6$. Finally, we give in Figure 4 computational times in second of the \texttt{LinsolveTriU\_Vec} with $\mathbf{A} \in (\mathcal{M}_{d,d}(K))^N$, $\mathbf{B} \in (\mathcal{M}_{d,1}(K))^N$, for $N = 10^6$ and $d \in [2,10]$.}

4 Factorizations

The object of this section is to present vectorized algorithms which compute factorizations (Cholesky or LU with partial pivoting) of all matrices contained in a 3D-array.

4.1 Cholesky factorization

Firstly we recall the classical Cholesky factorization. Let $B$ be a hermitian, positive-definite matrix in $\mathcal{M}_n(\mathbb{C})$. One can apply the Cholesky factorization: there exists a unique lower triangular matrix $L \in \mathcal{M}_n(\mathbb{C})$ with real and positive diagonal entries such that

$$B = LL^*.$$  \hfill (21)

With this factorization, the determinant of the matrix $B$ computes easily as $L$ is a lower triangular matrix:

$$\text{det}(B) = \text{det}(L)^2 = \left( \prod_{i=1}^{n} L_{i,i} \right)^2.$$  \hfill (22)

To compute the lower triangular matrix $L$ we use the following formula

$$L_{j,j} = \sqrt{B_{j,j} - \sum_{k=1}^{j-1} L_{j,k}L_{j,k}^*}$$

$$L_{i,j} = \frac{1}{L_{j,j}} \left( B_{i,j} - \sum_{k=1}^{j-1} L_{i,k}L_{j,k}^* \right) \text{ for } i > j.$$ 

In Algorithm 29 the Cholesky–Crout algorithm is given to compute the matrix $L$. It starts from the upper left corner of the matrix $L$ and proceeds to calculate the matrix column by column.
Algorithm 29 Function \texttt{Cholesky}. Computes the lower triangular matrix $L \in \mathcal{M}_n(\mathbb{C})$ such that $B = LL^*.$

\textbf{Données :} $B$ : a hermitian, positive-definite matrix in $\mathcal{M}_n(\mathbb{C})$.

\textbf{Résultat :} $L$ : the lower triangular matrix $L \in \mathcal{M}_n(\mathbb{C})$ with $L(i, i) > 0, \forall i \in [1, n]$.

1: \textbf{Function} $L \leftarrow \texttt{Cholesky}(B)$
2: $L \leftarrow \texttt{Zeros}(n, n)$
3: for $j \leftarrow 1$ to $n$ do $\triangleright$ Computes the $j$-th column of $L$
4: $S_1 \leftarrow 0$
5: for $l \leftarrow 1$ to $j - 1$ do
6: $S_1 \leftarrow S_1 + |L(j, l)|^2$
7: end for
8: $L(j, j) \leftarrow \texttt{sqrt}(B(j, j) - S_1)$
9: for $i \leftarrow j + 1$ to $n$ do
10: $S_2 \leftarrow 0$
11: for $l \leftarrow 1$ to $j - 1$ do
12: $S_2 \leftarrow S_2 + L(i, l) \cdot \texttt{Conj}(L(j, l))$
13: end for
14: $L(i, j) \leftarrow (B(i, j) - S_2) / L(j, j)$.
15: end for
16: end for
17: end \textbf{Function}

After these reminders, we present the heart of the matter. Let $A \in (\mathcal{M}_{d,d}(\mathbb{C}))^N$ be a hermitian positive definite 3D-array:

$$\forall k \in [1, N], A(k, :, :) = A_k \in \mathcal{M}_n(\mathbb{C})$$

is a hermitian positive definite matrix $\forall k \in [1, N], A(k, :, :) = A_k \in \mathcal{M}_n(\mathbb{C})$ with real and positive diagonal entries (i.e. $\forall k \in [1, N], A(k, :, :) = L_k \in \mathcal{M}_n(\mathbb{C})$ are lower triangular matrices with real and positive diagonal entries) such that

$$\forall k \in [1, N], A_k = L_k L_k^*$$

A non-vectorized function using the function \texttt{Cholesky} defined in Algorithm 29 is given in Algorithm 30. To introduce the vectorized code, we firstly present in Algorithm 31 an other non-vectorized version without using the function \texttt{Cholesky} : this is nothing but the copy of the function in the code.

As $N \gg d,$ vectorization of the Algorithm 31 consists to firstly permute the $k$ loop over $[1, N]$ with the $j$ loop over $[1, d]$ and then to vectorize the $k$ loop. In this case vectorization is immediate and given in Algorithm 32. The only remaining loops are very small loops and not need to be vectorized.
Algorithm 30 Function \texttt{Cholesky\_Mat}, returns cholesky factorizations of $A_k$ matrices (not vectorized)

\textbf{Input} $A$ : $N$-by-$d$-by-$d$ 3D array such that $A(k,:,:) = A_k$, $\forall k \in [1,N]$.

\textbf{Output} $L$ : $aN$-by-$d$-by-$d$ 3D array such that $\forall k \in [1,N]$, $L_k = L(k,:,:)$ and $A_k = L_k \odot L_k^T$.

\begin{verbatim}
Function $L \leftarrow \texttt{Cholesky\_Mat}(A)$
  for $k \leftarrow 1$ to $N$ do
    $L(k,:,:) \leftarrow \texttt{Cholesky}(A(k,:,:))$
  end for
end Function
\end{verbatim}

Algorithm 31 Function \texttt{Cholesky\_Cpt}, returns cholesky factorizations of $A_k$ matrices (not vectorized)

\begin{verbatim}
Function $L \leftarrow \texttt{Cholesky\_Cpt}(A)$
  for $k \leftarrow 1$ to $N$ do
    for $j \leftarrow 1$ to $d$ do
      $S_1 \leftarrow 0$
      for $l \leftarrow 1$ to $j - 1$ do
        $S_1 \leftarrow S_1 + |L(k,j,l)|^2$
      end for
      $L(k,j,j) \leftarrow \texttt{sqrt}(A(k,j,j) - S_1)$
    end for
    for $j \leftarrow 1$ to $d$ do
      $S_2 \leftarrow 0$
      for $l \leftarrow 1$ to $j - 1$ do
        $S_2 \leftarrow S_2 + L(k,i,l) * \texttt{Conj}(L(k,j,l))$
      end for
      $L(k,i,j) \leftarrow (B(k,i,j) - S_2)/L(k,j,j)$.
      end for
  end for
end Function
\end{verbatim}
Algorithm 32 Function Cholesky_Vec, returns cholesky factorizations of A matrices (vectorized)

1: Function L ← Cholesky_Vec (A)
2: L ← Zeros(N, d, d)
3: for j ← 1 to d do
4:    Sj ← Zeros(N)
5:    for l ← 1 to j − 1 do
6:       Sj ← Sj + |L(:, j, l)|^2
7:    end for
8:    L(:, j, j) ← sqrt(A(:, j, j) − Sj)
9: for i ← j + 1 to d do
10:   S2 ← Zeros(N)
11:   for l ← 1 to j − 1 do
12:      S2 ← S2 + L(:, i, l) .* conj(L(:, j, l))
13:   end for
14:   L(:, i, j) ← (A(:, i, j) − S2) ./ L(:, j, j).
15: end for
16: end for
17: end Function

In Table [17] computational time in second for the three functions Cholesky_Cpt, Cholesky_Mat and Cholesky_Vec under Matlab, Octave and Python are given with input data in (M_{3 d}(K))^N and for N up to 10^5. As expected the function Cholesky_Vec is the fastest. In Table [18] computational time in second of the Cholesky_Vec function is given for N values up to 10^7. Furthermore the numpy.linalg.cholesky Python function natively support Cholesky factorization on 3D-arrays and we added its computational times in Table [18] under the reference Python[Nat]. As we can see Matlab performs better but this is partially due to its multithreading capacities (see Table [19]). Finally, we give in Figure 5 the computation time in second of the Cholesky_Vec with input data in (M_{d, d}(K))^N for N = 10^6 and d ∈ [2, 10].

4.2 LU factorization with partial pivoting

At first we briefly recall results on LU factorization with partial pivoting. Let A ∈ M_d(C) (not necessarily regular). The LU factorization with partial pivoting, described in [1, 2], is a well known method which allows to compute a permutation matrix P ∈ M_d(R), a lower triangular matrix L ∈ M_d(C) with unit diagonal and an upper triangular matrix U ∈ M_d(C) such that

\[ PA = LU. \] (23)

In Algorithm 33 a classical computation of the three matrices P, L and U is proposed. Thereafter, the less memory consuming Algorithm 34 is given where U is stored in the upper triangle of A and L in the strictly lower triangle of A.

The object of this section is to describe a vectorized version of these two algorithms apply to 3D-arrays. More precisely, let A ∈ (M_{d, d}(K))^N, we want to compute the three 3D-arrays P, L and U in (M_{d, d}(K))^N such that, for all

13: end if
14: end for
15: end Function

Unlike the cholesky decomposition, there is currently no Numpy / Scipy Python function calculating a LU factorization for an 3D-array.

4.2.1 Full computation

Firstly, we give Algorithm 35, a trivial but not vectorized version of the Algorithm 33 apply to the 3D-array \(A \in (\mathcal{M}_{d,d}(K))^N\). This code use on each matrix \(A(k, :)\) the function \(\textsc{palu}\) described in Algorithm 33. Before vectorizing, one have to write the complet code without using this function. This is done in Algorithm 36.

Algorithm 35 Function *\textsc{palu_mat}* computes all \(LU\) factorizations with partial pivoting of a 3D-array \(A\) such that \(P_k A_k = L_k U_k\)

Input \(A\) : in \((\mathcal{M}_{d,d}(K))^N\).

Output \(P\) : permutation matrices in \((\mathcal{M}_{d,d}(K))^N\),
\(L\) : lower triangular matrices in \((\mathcal{M}_{d,d}(K))^N\)
avec \(L_k(i, i) = 1, \forall i \in [1, d]\),
\(U\) : upper triangular matrices in \((\mathcal{M}_{d,d}(K))^N\).

1: Function \([P, L, U] \leftarrow \textsc{palu_mat} (A)\]
2: for \(k \leftarrow 1\) to \(N\) do
3: \([P(k, :, :), L(k, :, :), U(k, :, :)] \leftarrow \textsc{palu}(A(k, :, :))\]
4: end for
5: end Function
Algorithm 36 Function $\text{PALU}_\text{Cpt}$ computes all $LU$ factorizations with partial pivoting of a 3D-array $A$ such that $P_kA_k = L_kU_k$

1: Function $[P, L, U] \leftarrow \text{PALU}_\text{Cpt}(A)$
2: for $k \leftarrow 1$ to $N$ do
3:    for $i \leftarrow 1$ to $d$ do
4:        $\mu \leftarrow \text{Argmax}(|U(k,i:i,d)|) + (i-1)$
5:        if $|U(k,\mu,i)| > \epsilon$ then
6:            if $\mu \neq i$ then $\triangleright$ Permutates rows $i$ and $\mu$
7:                $U(k,i:i:d) \leftarrow U(k,\mu,i:d)$ $\triangleright$ Only columns $i$ to $d$
8:                $L(k,1:i-1) \leftarrow L(k,\mu,1:i-1)$ $\triangleright$ Only columns $1$ to $i-1$
9:            $P(k,i,:) \leftrightarrow P(k,\mu,:)$ $\triangleright$ All columns
10:        end if
11:    for $j \leftarrow i + 1$ to $d$ do $\triangleright$ Elimination
12:        $L(k,j,i) \leftarrow U(k,j,i)/U(k,i,i)$
13:        $L(k,j,i:d) \leftarrow U(k,j,i:d) - L(k,j,i) * U(k,i,i:nd)$
14:    end for
15: end if
16: end for
17: end for
18: end Function

As $N \gg n$, the vectorization of the Algorithm 36 consists in removing the $k$ loop over the $N$ matrices. Thereafter we permute the $i$ loop with the $k$ loop. Let $i \in [1,d]$, finding all pivoting index for each matrix on column $i$ and rows $i:d$ on a not vectorized way is:

\[ \mu(k) \leftarrow \text{Argmax}(|U(k,i:i,d)|) + (i-1), \quad \forall k \in [1,N] \]

Vectorization is obtained via the $\text{Argmax}$ function by searching arg max values on 2D-array $|U(:,i:i,d)|$ along 2-nth dimension (axis):

\[ \mu \leftarrow \text{Argmax}(|U(:,i:i,d)|,2) + (i-1). \]

Permutation at step $i$ for $P$ is

\[ P(k,i,:) \leftrightarrow P(k,\mu(k,:),) \quad \forall k \in [1,N] \]

This can be written as

for $j \leftarrow 1$ to $d$ do
    $P(k,i,j) \leftrightarrow P(k,\mu(k),j), \quad \forall k \in [1,N]$
end for

So there are $N \times d$ permutations to do and thus we must use linear index access to $P$ elements for vectorizing a such operation.

$J \leftarrow \text{ONES}(1,N)$

for $j \leftarrow 1$ to $d$ do
    $I_1 \leftarrow \text{Sub2Ind}([N,d,d],1:N,\mu,j*J)$
    $I_2 \leftarrow \text{Sub2Ind}([N,d,d],1:N,i*J,j*J)$
    $P(I_1) \leftrightarrow P(I_2)$
end for
Permutation rows for $L$ and $U$ are obtained in a similar way.

Finally the elimination loop (Algorithm 36, lines [11] to [14]) is only done for all indices $k \in [1, N]$ such that $|U(k, i, i)| > \epsilon$ and we obtain the following vectorization:

$$K \leftarrow |U(\cdot, i, i)| > \epsilon$$

for $j \leftarrow i + 1$ to $d$ do

$$L(K, j, i) \leftarrow U(K, j, i) . / U(K, i, i)$$

$$L(K, j, i : d) \leftarrow U(K, j, i : d) - L(K, j, i) . * U(K, i, i : d)$$

end for

The complete vectorized code is given by `PALU_Vec` function in Algorithm 37.

**Algorithm 37** Function `PALU_Vec` computes all $LU$ factorizations with partial pivoting of a 3D-array $A$ such that $P_k A_k = L_k U_k$

1: Function [$P, L, U$] $\leftarrow$ `PALU_Vec` ( $A$ )
2: $K \leftarrow 1 : N$
3: $J$ $\leftarrow$ `ones`(1, N)
4: for $i$ $\leftarrow 1$ to $d$ do

5: $\mu \leftarrow \text{argmax}(|U(\cdot, i : d, i)|, 2) + (i - 1)$
6: for $j$ $\leftarrow 1$ to $i - 1$ do

7: $I_1 \leftarrow \text{sub2ind}([N, d, d], K, \mu, j \ast J)$
8: $I_2 \leftarrow \text{sub2ind}([N, d, d], K, i \ast J, j \ast J)$
9: $L(I_1) \leftarrow L(I_2)$
10: $P(I_1) \leftarrow P(I_2)$
11: end for

12: for $j$ $\leftarrow i + 1$ to $d$ do

13: $I_1 \leftarrow \text{sub2ind}([N, d, d], K, \mu, j \ast J)$
14: $I_2 \leftarrow \text{sub2ind}([N, d, d], K, i \ast J, j \ast J)$
15: $U(I_1) \leftarrow U(I_2)$
16: $P(I_1) \leftarrow P(I_2)$
17: end for

18: $Kidx \leftarrow |U(\cdot, i, i)| > \epsilon$
19: for $j$ $\leftarrow i + 1$ to $d$ do

20: $L(Kidx, j, i) \leftarrow U(Kidx, j, i) . / U(Kidx, i, i)$
21: $L(Kidx, j, i : d) \leftarrow U(Kidx, j, i : d) - L(Kidx, i, i : d) . * U(Kidx, i, i : d)$
22: end for

23: end for

24: end Function

In Table 20 the computation time in second for the three functions `PALU_Cpt`, `PALU_Mat` and `PALU_Vec` under Matlab, Octave and Python are given with input data in $(M_{3,3}(K))^N$. As expected the function `PALU_Vec` is the fastest. In Table 21 the computation time in second for `PALU_Vec` is given for $N$ values up to $10^7$. Finally, we give in Figure 6 the computation time in second of the `PALU_Vec` with input data in $(M_{d,d}(K))^N$ for $N = 10^8$ and $d \in [2,10]$.

4.2.2 Inplace computation

From Algorithm 34 we immediately obtain the not vectorized Algorithm 38 for a 3D-array $\mathbf{A} \in (\mathcal{M}_{d,d}(K))^N$. Before vectorizing, one have to write the complete code without using this function. This is done in Algorithm 39.

**Algorithm 38**

Function `pLUNPLACE_MAT` computes all LU factorizations with partial pivoting of a 3D-array $\mathbf{A}$ such that $P_k \mathbf{A}_k = L_k U_k$.

**Input**

- $\mathbf{A}$ : in $(\mathcal{M}_{d,d}(K))^N$.

**Output**

- $\mathbf{p}$ : permutation index array in $(\mathcal{M}_d(K))^N$.
- $\mathbf{A}$ : the modified 3D-array

1: Function $[\mathbf{p}, \mathbf{A}] \leftarrow pLUNPLACE_MAT\left( \mathbf{A} \right)$
2: for $k \leftarrow 1$ to $N$ do
3: \hspace{1em} $[\mathbf{p}(k,:), \mathbf{A}(k,:,:)] \leftarrow pLUNPLACE(\mathbf{A}(k,:,))$
4: end for
5: end Function
Algorithm 39 Function $\texttt{pLUinplace\_Cpt}$ computes all LU factorizations with partial pivoting of a 3D-array $\mathbf{A}$ such that $P_k A_k = L_k U_k$

1: Function $[\mathbf{p}, \mathbf{A}] \leftarrow \texttt{pLUinplace\_Cpt}(\mathbf{A})$
2: $\mathbf{p} \leftarrow \texttt{RepTile}(1 : n, N, 1)$
3: for $k \leftarrow 1$ to $N$
4: for $i \leftarrow 1$ to $n - 1$
5: $\mu \leftarrow \texttt{Argmax}(\mathbf{A}(k, i : n, i)) + (i - 1)$
6: if $|\mathbf{A}(k, \mu, i)| > \epsilon$
7: if $\mu \neq i$
8: $\mathbf{A}(k, i, :)$ $\leftrightarrow$ $\mathbf{A}(k, \mu, :)$
9: $\mathbf{p}(k, i) \leftrightarrow \mathbf{p}(k, \mu)$
10: end if
11: $I \leftarrow i + 1 : n$
12: $\mathbf{A}(k, I, i) \leftarrow \mathbf{A}(k, I, i)/\mathbf{A}(k, i, i)$
13: $\mathbf{A}(k, I, I) \leftarrow \mathbf{A}(k, I, I) - \mathbf{A}(k, I, i) * \mathbf{A}(k, i, I)$
14: end if
15: end for
16: end for
17: end Function

The complete vectorized code is given by $\texttt{pLUinplace\_Vec}$ function in Algorithm 40 and is close to the $\texttt{PALU\_Vec}$ function given in Algorithm 37.

Algorithm 40 Function $\texttt{pLUinplace\_Vec}$ computes all LU factorizations with partial pivoting of a 3D-array $\mathbf{A}$ such that $P_k A_k = L_k U_k$

1: Function $[\mathbf{p}, \mathbf{A}] \leftarrow \texttt{pLUinplace\_Vec}(\mathbf{A})$
2: $\mathbf{p} \leftarrow \texttt{RepTile}(1 : d, N, 1)$
3: $\mathbf{K} \leftarrow 1 : N$
4: $\mathbf{J} \leftarrow \texttt{Ones}(1, N)$
5: for $i \leftarrow 1$ to $n - 1$
6: $\mu \leftarrow \texttt{Argmax}(|U(:, i : d, i)|, 2) + (i - 1)$
7: for $j \leftarrow 1$ to $d$
8: $I_1 \leftarrow \texttt{Sub2Ind}([N, d, d], \mathbf{K}, \mu, j * \mathbf{J})$
9: $I_2 \leftarrow \texttt{Sub2Ind}([N, d, d], \mathbf{K}, i * \mathbf{J}, j * \mathbf{J})$
10: $\mathbf{A}(I_1) \leftrightarrow \mathbf{A}(I_2)$
11: end for
12: $I_1 \leftarrow \texttt{Sub2Ind}([N, d, d], \mathbf{K}, \mu)$
13: $I_2 \leftarrow \texttt{Sub2Ind}([N, d, d], \mathbf{K}, i * \mathbf{J})$
14: $\mathbf{p}(I_1) \leftrightarrow \mathbf{p}(I_2)$
15: $\mathbf{Kidx} \leftarrow |U(:, i, i)| > \epsilon$
16: for $j \leftarrow i + 1$ to $d$
17: $L(K\texttt{idx}, j, i) \leftarrow U(K\texttt{idx}, j, i) / U(K\texttt{idx}, i, i)$
18: $L(K\texttt{idx}, j, i : d) \leftarrow U(K\texttt{idx}, j, i : d) - L(K\texttt{idx}, j, i) * U(K\texttt{idx}, i, i : d)$
19: end for
20: end for
21: end Function
In Table 23 the computation time in second for the three functions `pLUinplace_Cpt`, `pLUinplace_Mat` and `pLUinplace_Vec` under Matlab, Octave and Python are given with input data in \( (M_{3,3}(k))^N \). As expected the function `pLUinplace_Vec` is the fastest. In Table 24 the computation time in second for `pLUinplace_Vec` is given for \( N \) values up to \( 10^6 \). In Table 23 the effects of multithreading on cpu times is given. Finally, we give in Figure 2 the computation time in second of the `pLUinplace_Vec` with input data in \( (M_{d,d}(k))^N \) for \( N = 10^6 \) and \( d \in [2, 10] \).

Table 25: Function `pLUinplace_Vec` with \( A \in (M_{3,3}(k))^N \) under Matlab 2018a: effect of multithreaded on cpu times.
5 Linear solvers

To solve linear system one can use the LU factorization with partial pivoting for regular matrices or the cholesky factorization for symmetric positive definite matrices.

Let $B \in (\mathcal{M}_{d,n}(K))^N$ or $B \in \mathcal{M}_{d,n}(K)$, we want to solve the equation

$$AX = B$$

as described in section 1.2.3.

5.1 Using Cholesky factorization

Let $A \in \mathcal{M}_{d,d}(K)$ be symmetric positive definite matrix and $B \in \mathcal{M}_{d,n}(K)$. As seen in 4.1, there exists an unique lower triangular matrix $L$ with strictly positive diagonal elements such that $A = LL^*$. So, to solve the equation

$$AX = B$$

one just have to solve the two triangular systems

$$LY = B \text{ then } L^*X = Y.$$
uses the vectorized functions \texttt{Cholesky_Vec}, \texttt{LinsolveTriL_Vec}, \texttt{LinsolveTriU_Vec} and \texttt{ctranspose_Vec} respectively given in Algorithms 32, 28 and 28. In Table 26, computational times in second with $A \in (M_{3,3}(K))^N$ and $B \in (M_{3,1}(K))^N$ under Matlab, Octave and Python are given for $N$ values up to $10^7$. In Figure 8, the computation time in second of the \texttt{LinsolveCholesky_Vec} with $A \in (M_{d,d}(K))^N$ and $B \in (M_{d,1}(K))^N$ for $N = 10^6$ and $d \in [2, 10]$ is represented.

**Algorithm 41** Function \texttt{LinsolveCholesky_Vec}, solves equation $AX = B$ where $A$ is a symmetric positive definite 3D-array(vectorized)

\begin{verbatim}
Function X = LinsolveCholesky_Vec(A, B)
  L = Cholesky_Vec(A)
  Y = LinsolveTriL_Vec(L, B)
  X = LinsolveTriU_Vec(ctranspose_Vec(L), Y)
end Function
\end{verbatim}

</tbody>
</table>

Table 26: Computational times in seconds of the \texttt{LinsolveCholesky_Vec} function with $A \in (M_{3,d}(K))^N$ and $B \in (M_{d,1}(K))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

5.2 Using LU factorization with partial pivoting

Let $A \in M_{d,d}(K)$ be a regular matrix and $B \in M_{d,n}(K)$. As seen in 4.2, there exists a permutation matrix $P$, a lower triangular matrix $L$ with unit diagonal and a upper triangular matrix $U$ such that $PA = LU$. So, to solve the equation $AX = B$ one just have to solve the two triangular systems $LY = B$ then $UX = Y$.

For a regular 3D-array we immediately deduce the \texttt{LinsolvePALU_Vec} vectorized function given in vectorized Algorithm 42. This function uses the vectorized functions \texttt{PALU_Vec}, \texttt{LinsolveTriL_Vec} and \texttt{LinsolveTriU_Vec} respectively given in Algorithms 37, 24 and 28. In Table 27, computational times in second with $A \in (M_{3,3}(K))^N$ and $B \in (M_{3,1}(K))^N$ under Matlab, Octave and Python are given for $N$ values up to $10^7$. Furthermore with Python, the broadcasting rules can be applied by using the \texttt{numpy.linalg.solve} function that we
Figure 8: Computational times in seconds of \texttt{LINSOLVE_CHOLESKY_VEC} function with $\mathbf{A} \in (\mathcal{M}_{d,d}(\mathbb{K}))^N$ with $N = 10^6$ and $d \in [2, 10]$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
denote by «Python[Nat]» in the Table. In Figure 9 the computation time in second of the LINSOLVE_PALU_VEC with \( \mathbf{A} \in (M_{d,d}(K))^N \) and \( \mathbf{B} \in (M_{d,1}(K))^N \) for \( N = 10^6 \) and \( d \in [2, 10]^2 \) is represented.

Table 27: Computational times in seconds of the LINSOLVE_PALU_VEC function with \( \mathbf{A} \in (M_{3,3}(K))^N \) and \( \mathbf{B} \in (M_{3,1}(K))^N \) for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. The last column is for the native python function numpy.linalg.solve.
Figure 9: Computational times in seconds of LINSOLVE\_PALU\_VEC function with $A \in (M_{d,d}(K))^N$ with $N = 10^6$ and $d \in [2,10]$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
6 Determinants

The purpose of this section is to compute determinant of an 3D-array as defined in section 1.2.1. In vectorized languages including a determinant function \( \text{Det} \) for a matrix in \( \mathcal{M}_d(K) \), a non-vectorized code is easy to write and it is given in Algorithm 43. However, as \( N \) supposed to be very large compared to \( d \) we must vectorized determinants computation. It should be noted that the `numpy.linalg.det` Python function of the Numpy package can performed directly this operation.

Algorithm 43 Function \( \text{Det}_\text{Mat} \), returns determinants of a 3D-array (not vectorized)

Input \( \mathbf{A} \) : in \( (\mathcal{M}_{d,d}(K))^N \)

Output \( \mathbf{D} \) : in \( \mathbb{R}^N \)

Function \( \mathbf{D} \leftarrow \text{Det}_\text{Mat}(\mathbf{A}) \)
for \( k \leftarrow 1 \) to \( N \) do
\( \mathbf{D}(k) \leftarrow \text{Det}(\mathbf{A}(k,:,:)) \)
end for
end Function

6.1 Vectorized algorithm using the Laplace expansion

To compute the determinant of a matrix \( \mathbf{B} \in \mathcal{M}_n(\mathbb{R}) \) we can use the Laplace expansion algorithm. For example the formula, expanded with respect to the \( i \)-th row is

\[
\det \mathbf{B} = \sum_{j=1}^{n} b_{i,j} C_{i,j} \overset{\text{def}}{=} \det_1 \mathbf{B}
\]

(24)

where the \( C_{i,j} \) scalar is the \( (i, j) \) cofactor of \( \mathbf{B} \). More precisely we have

\[
C_{i,j} = (-1)^{i+j} M_{i,j}
\]

where \( M_{i,j} \) is the \( (i, j) \) minor of \( \mathbf{B} \) which is the determinant of the matrix formed by deleting the \( i \)-th row and the \( j \)-th columns of \( \mathbf{B} \). We give in Algorithm 44 the recursive function \( \text{DetLap} \) using the formula (24).

For a 3D-array \( \mathbf{A} \) in \( (\mathcal{M}_{d,d}(K))^N \), we deduce the two non-vectorized function using the \( \text{DetLap} \) function given in Algorithms 45 and 46. From the last one, we easily obtain the vectorized function \( \text{DetLap}_\text{Vec} \) given in Algorithm 47.
To overcome, instead of creating a new 3D array from object of Algorithm 48, we only create a row and column indices as 1D arrays. This is the expanded with respect to the 1st row.

The major disadvantage of the Algorithm 47 is that it is memory consuming. To overcome, instead of creating a new 3D array from $A$ when calling recursively the function, we only create a row and column indices as 1D arrays. This is the object of the Algorithm 48.

Algorithm 44: Function $\text{DetLap}_M$, returns determinant of the matrix $B$ by using Laplace formula (24) expanded with respect to the 1st row.

Function $B$ : a $d$-by-$d$ matrix
Output $r$ : the scalar $\det(B)$.

if $d = 1$ then
  $r = B(1,1)$
else
  $r = 0$
  for $j = 1$ to $d$
    $r = r + (-1)^{j+1} \times B(1,j) \times \text{DetLap}(B(2:d,[1:j-1,j+1:d]))$
  end for
end if

Algorithm 45: Function $\text{DetLap}_M(r)$, returns determinants of a 3D-array (not vectorized).

Function $D$ : in $(M_{d \times d}(K))^N$
Output $r$ : in $K^N$

if $d = 1$ then
  $D = A$
else
  $D = \text{zeros}(N,1)$
  for $k = 1$ to $N$
    $D[k] = D[k] + (-1)^{k+1} \times A(k,k,1:j:1)$
  end for
end if

Algorithm 46: Function $\text{DetLap}_V(r)$, returns determinants of a 3D-array in $(M_{d \times d}(K))^N$ (not vectorized).

Function $D$ : in $(M_{d \times d}(K))^N$
Output $r$ : in $K^N$

if $d = 1$ then
  $D = A$
else
  $D = \text{zeros}(N,1)$
  for $j = 1$ to $d$
    $D[j] = D[j] + (-1)^{j+1} \times A(:,j,1:j:1)$
  end for
end if

Algorithm 47: Function $\text{DetLap}_V(r)$, returns determinants of a 3D-array in $(M_{d \times d}(K))^N$ (not vectorized).

Function $D$ : in $(M_{d \times d}(K))^N$
Output $r$ : in $K^N$

if $d = 1$ then
  $D = A$
else
  $D = \text{zeros}(N,1)$
  for $j = 1$ to $d$
    $D[j] = D[j] + (-1)^{j+1} \times A(:,j,1:j:1)$
  end for
end if

Algorithm 48: Function $\text{DetLap}_V(r)$, returns determinants of $A$ matrices by using Laplace formula (24) expanded with respect to the 1st row (vectorized, recursive and memory safe).

Input $A$ : in $(M_{d \times d}(K))^N$
$A$ : (optional) row indices, default 1:$d$.
Always the same size as $J$.
$J$ : (optional) column indices, default 1:$d$.
Always the same size as $I$.
Output $D$ : in $K^N$

if $I = \emptyset$ and $J = \emptyset$ then
  $m = d$
else
  $m = \text{Len}(I)$
end if

if $m = 1$ then
  $D = A(:,(1),J(1))$
else
  $D = \text{zeros}(1,N)$
  for $j = 1$ to $m$
    $D[j] = D[j] + (-1)^{j+1} \times A(:,(I(j)),J(j))$
  end for
end if

Table 30: Computational times in seconds of `DetLAP_Vec` functions with $A \in \mathbb{M}_{3,3}(\mathbb{K})^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. The last column is for the native python function `numpy.linalg.det`. 46
Figure 10: Computational times in seconds of $\text{DetLapId}_x \text{Vec}$ function with $\mathbf{A} \in (\mathcal{M}_{d,d}(K))^N$ with $N = 10^6$ and $d \in [2, 10]$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
6.2 Using \(LU\) factorization

An other way in calculating determinant of a matrix is to use the \(LU\) factorization with partial pivoting. Indeed we have

\[
PA = LU,
\]

where \(P \in \mathcal{M}_d(\mathbb{R})\) is a permutation matrix, \(L \in \mathcal{M}_d(\mathbb{C})\) is a lower triangular matrix with unit diagonal and \(U \in \mathcal{M}_d(\mathbb{C})\) is an upper triangular matrix. So we obtain

\[
\det P \det A = \det L \det U
\]

As \(P\) is a permutation matrix we have

\[
\det P = \pm 1
\]

and we The parity (oddness or evenness) of a permutation \(\sigma\) of \([1, d]\) can be defined as the parity of the number of inversions for \(\sigma\), i.e., of pairs of elements \(i, j\) of \([1, d]\) such that \(i < j\) and \(\sigma(i) > \sigma(j)\). The sign or signature of a permutation \(\sigma\) is denoted \(\text{sign}(\sigma)\) and defined as +1 if \(\sigma\) is even and −1 if \(\sigma\) is odd.

Table 31: Computational times in seconds of \(\textbf{DetPLUIN\_VEC}\) function with \(A \in (\mathcal{M}_{3,3}(\mathbb{K}))^N\) for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. The last column is for the native python function \texttt{numpy.linalg.det}.

6.3 Vectorized algorithm using another expansion

In [3], an other expansion to compute the determinant of a matrix \(\mathbb{B} \in \mathcal{M}_n(\mathbb{R})\) is given by

\[
\det \mathbb{B} = \frac{\det(\mathbb{B}[1,1]) \det(\mathbb{B}[n,n]) - \det(\mathbb{B}[1,n]) \det(\mathbb{B}[n,1])}{\det(\mathbb{B}[2,2])} \overset{dd}{=} \text{det}_2 \mathbb{B} \tag{26}
\]

where \(\mathbb{B}[i,j]\) is the matrix formed by deleting the \(i\)-th row and the \(j\)-th columns of \(\mathbb{B}\) and \(\mathbb{B}[2,2]\) is the submatrix of \(\mathbb{B}\) formed by deleting rows \(1, n\) and columns \(1, n\) of \(\mathbb{B}\). This formula is not really useful as a divide by zero is always possible even if the matrix \(\mathbb{B}\) is symmetric positive definite. For example for any symmetric positive definite matrix \(\mathbb{B} \in \mathcal{M}_4(\mathbb{R})\) such that \(\mathbb{B}_{2,3} = \mathbb{B}_{3,2} = 0\) a division by zero occurs in computation of \(\det(\mathbb{B}[n,n])\). Try the identity matrix!

However when the matrix \(\mathbb{B}\) is symmetric positive definite one can mixed formulas (24) and (26) to obtain

\[
\det \mathbb{B} = \frac{\text{det}_2(\mathbb{B}[1,1]) \text{det}_2(\mathbb{B}[n,n]) - \text{det}_4(\mathbb{B}[n,1])^2}{\text{det}_4(\mathbb{B}[2,2])} \overset{dd}{=} \text{det}_3 \mathbb{B} \tag{27}
\]

48
Figure 11: Computational times in seconds of \texttt{DetpLUinplace} function with $\mathbf{A} \in (\mathcal{M}_{d,d}(\mathbb{K}))^N$ with $N = 10^6$ and $d \in [2,10]$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
It is clear that the matrices $M_{r_1r_1}$, $M_{n_1}$, and $B_{r_2s}$ are also symmetric positive definite. Due to symmetry we have $M_{n_1} = M_{r_1r_1}$ but this matrix is not symmetric positive definite and so if we apply formula (26) on it a division by zero may occur. To overcome this problem we used formula (24) to compute the determinant of $M_{n_1}$.

We give in Algorithm 49 the recursive function using the formula (27).

**Algorithm 49** Function $detMixed$, returns determinant of the symmetric/hermitian positive definite matrix $B$ by using formula (27).

**Input** $B$ : a $n$-by-$n$ matrix

**Output** $r$ : the scalar $det(B)$.

```plaintext
Function $r ← detMixed(B)$
if $n = 1$ then
    $r ← B(1, 1)$
else if $n = 2$ then
    $r ← B(1, 1) \cdot B(2, 2) - B(1, 2) \cdot B(2, 1)$
else
    $r ← detMixed(B(2 : n, 2 : n)) \cdot detMixed(B(1 : n - 1, 1 : n - 1))$
    $r ← r - detLaplace(B(1 : n - 1, 2 : n))^2$
    $r ← r / detMixed(B(2 : n - 1, 2 : n - 1))$
end if
end Function
```

A first vectorized and recursive function using the 3D array $A$ is easy to write and it is given in Algorithm 50.

**Algorithm 50** Function $detMix_Vec$, returns determinants of symmetric/hermitian positive definite matrices $A_k$ by using formula (27) (vectorized and recursive).

**Input** $A$ : $N$-by-$d$-by-$d$ 3D array such that $A(k,:,:) = A_k$, $\forall k \in [1,N]$.

**Output** $D$ : array of size $N$ such that $D(k) = det(A_k)$, $\forall k \in [1,N]$.

```plaintext
Function $D ← detMix_Vec(A)$
if $d = 1$ then
    $D ← A(:, 1, 1)$
else if $d = 2$ then
    $D ← A(:, 1, 1) \cdot A(:, 2, 2) - A(:, 1, 2) \cdot A(:, 2, 1)$
else
    $I_1 ← 2 : d$, $I_d ← 1 : d - 1$, $I_1d ← 2 : d - 1$
    $D ← detMix_Vec(A(:, I_1, I_1)) \cdot detMix_Vec(A(:, I_d, I_d))$
    $D ← D - detLap_Vec(A(:, I_1, I_1))^2$
    $D ← D / detMix_Vec(A(:, I_1d, I_1d))$
end if
end Function
```

The major disadvantage of the Algorithm 50 is that it is memory consuming.
To overcome, instead of creating a new 3D array from \( A \) when calling recursively the function, we only create a row and column indices as 1D arrays. This is the object of the Algorithm 51.

**Algorithm 51** Function \texttt{detMix\_Vec\_v04}, returns determinants of the symmetric definite positive matrices \( A_k \) by using formula (26) (vectorized, recursive and memory safe).

**Input**
- \( A \) : \( N \)-by-\( d \)-by-\( d \) 3D array such that \( A(k,:,:)=A_k \), \( \forall k \in [1,N] \).
- \( I \) : (optional) row indices. default 1 : \( d \).
- \( J \) : (optional) column indices. default 1 : \( d \).

**Output**
- \( D \) : array of size \( N \) such that \( D(k)=\det(A_k) \), \( \forall k \in [1,N] \).

**Function** \( D \leftarrow \text{detMixIdx\_Vec}(A,I,J) \)

\[
\begin{align*}
\text{if } I &= \emptyset \text{ and } J = \emptyset \text{ then} \\
& m \leftarrow d \\
& I \leftarrow 1 : d, J \leftarrow 1 : d
\end{align*}
\]

**else**

\[
\begin{align*}
& m \leftarrow \text{len}(I)
\end{align*}
\]

**end if**

\[
\begin{align*}
\text{if } m &= 1 \text{ then} \\
& D \leftarrow A(:,1,1)
\end{align*}
\]

**else if** \( m = 2 \) **then**

\[
\begin{align*}
& D \leftarrow A(:,1,1) \cdot A(:,2,2) - A(:,1,2) \cdot A(:,2,1)
\end{align*}
\]

**else**

\[
\begin{align*}
& I_1 \leftarrow I(1 : m), \quad J_1 \leftarrow J(1 : m), \\
& I_d \leftarrow I(1 : m - 1), \quad J_d \leftarrow J(1 : m - 1), \\
& I_{1d} \leftarrow I(1 : m - 1), \quad J_{1d} \leftarrow J(1 : m - 1), \\
& D \leftarrow \text{detMixIdx\_Vec}(A,I_1,J_1) \cdot \text{detMixIdx\_Vec}(A,I_d,J_d) \\
& D \leftarrow D - \text{detLapIdx\_Vec}(A,I_1,J_d) \cdot 2 \\
& D \leftarrow D \cdot \text{detMixIdx\_Vec}(A,I_{1d},J_{1d})
\end{align*}
\]

**end if**

**end Function**

A Vectorized algorithmic language

A.1 Common operators and functions

We also provide below some common functions and operators of the vectorized algorithmic language used in this article which generalize the operations on scalars to higher dimensional arrays, matrices and vectors:

- `A ← B` Assignment
- `A * B` matrix multiplication,
- `A .* B` element-wise multiplication,
- `A ./ B` element-wise division,
- `A(:)` all the elements of `A`, regarded as a single column.
- `A^T` transpose of the matrix `A`.
- `[]` Horizontal concatenation,
- `[ ]` Vertical concatenation,
- `A(I, :)` `I`-th row of `A`.
- `Sum(A, dim)` sums along dimension `dim`.
- `Prod(A, dim)` product along dimension `dim`,
- `Size(A)` return the dimensions of the multi-array `A`.
- `Argmax(A, dim)` the arguments of the maxima along dimension `dim`,
- `Argmin(A, dim)` the arguments of the minimum along dimension `dim`,
- `I_{m \times n}` (or `I_n`) `m`-by-`n` identity matrix,
- `O_{m \times n}` (or `O_n`) `m`-by-`n` matrix or sparse matrix of zeros,
- `Ones(n_1, \ldots, n_{\ell})` `\ell` dimensional array of ones,
- `Zeros(n_1, \ldots, n_{\ell})` `\ell` dimensional array of zeros,
- `Repmat(A, m, n)` tiles the `p`-by-`q` array/matrix `A` to produce the `(m \times p)`-by-`(n \times q)` array composed of copies of `A`,
- `Reshape(A, m, n)` returns the `m`-by-`n` array/matrix whose elements are taken columnwise from `A`,
- `Det(A)` return the determinant of the square matrix `A`.
- `Sub2ind(dims, i_1, i_2, \ldots, i_d)` return the linear index corresponding to the provided subscripts of an array of dimensions `dims`. Here `d` is the number of dimensions i.e. the length of the `dims` array.
- `Ind2Sub(dims, index)` return the subscripts of corresponding to the provided linear index of an array of dimension `dims`.

In vectorized language broadcasting provides a means of vectorizing array operations so that looping occurs in low level language as C, Fortran. Element-wise operations between two multi-dimensional arrays are said to be compatible if the smaller array is broadcast across the larger array so that they have compatible dimensions. Let `A` be a `n_1`-by-`n_2`-by-\ldots-by-`n_a` array and `B` be a `m_1`-by-`m_2`-by-\ldots-by-`m_b` with `n_a \leq m_b`. These two arrays are compatible for element wise operations if

\[ n_i = m_i \text{ or } n_i = 1 \text{ or } m_i = 1, \quad \forall i \in [1, n_a] \]
Let \( \circ \) denote an element-wise binary operator. If the two arrays \( A \) and \( B \) are compatible then the following operations are allowed

\[
C \leftarrow A \circ B \quad \text{and} \quad D \leftarrow B \circ A.
\]

The result arrays \( C \) and \( D \) have the same dimension

\[
\max(n_1, m_1) \times \max(n_2, m_2) \times \ldots \times \max(n_a, m_a) \times m_{a+1} \times \ldots \times m_b
\]

### A.1.1 Sub2ind function

\[
I \leftarrow \text{Sub2ind}(d_1, \ldots, d_n, i_1, \ldots, i_n)
\]

returns the linear index \( I \) corresponding to the provided subscripts \( i_1, \ldots, i_n \) of an \( n \) multi-dimensional array of dimensions \( [d_1, \ldots, d_n] \). Subscripts \( i_1, \ldots, i_n \) must have the same size and index \( I \) will have this size. For example if \( A \) is a \( n \)-dimensional array and all subscripts \( i_1, \ldots, i_n \) are 1-dimensional array of dimension \( m \) then

\[
I \leftarrow \text{Sub2ind}(\text{Size}(A), i_1, \ldots, i_n)
\]

returns the linear index \( I \) which is the 1-dimensional array of dimension \( m \) such that

\[
A(I(k)) = A(i_1(k), \ldots, i_n(k)), \quad \forall k \in [1, m]
\]

where \( A(I(k)) \) is equivalent to \( B(I(k)) \) where \( B = A(:, \ldots, :) \).

### A.1.2 Ind2sub function

### A.2 Combinatorial functions

**Perms(\( V \))**

where \( V \) is an array of length \( n \). Returns a \( n! \)-by-\( n \) array containing all permutations of \( V \) elements.

The lexicographical order is chosen.

**Combs(\( V, k \))**

where \( V \) is an array of length \( n \) and \( k \in [1, n] \).

Returns a \( \frac{n!}{(n-k)!} \)-by-\( k \) array containing all combinations of \( n \) elements taken \( k \) at a time. The lexicographical order is chosen.

List of algorithms

1. Function **AXpBY_Cpt**, returns linear combination $\alpha X + \beta Y$ by
   using component by component computation. .................. 8
2. Function **getCpt**, returns component $(i,j)$ of the $k$-th matrix
   of $X$ ....................................................... 8
3. Function **AXpBY_Cvt**, returns linear combination $\alpha X + \beta Y$ by
   converting arrays to a 3D-arrays. .............................. 9
4. Function **to3Darray**, converts to a 3DArray ..................... 9
5. Function **AXpBY_Mat**, returns linear combination $\alpha X + \beta Y$ by
   using vectorized operations on 2D-arrays or matrices. ...... 9
6. Function **getMat**, returns the $k$-th matrix of $X$ .......... 9
7. Function **AXpBY_Vec**, returns linear combination $\alpha X + \beta Y$ by
   using vectorized operations on 1D-arrays. .................... 9
8. Function **getVec**, returns $(i,j)$ components of $X$ ......... 9
Function `etimes_Cpt`, returns element by element operation \( X \odot Y \) by using function \( f : (x, y) \in K^2 \rightarrow x \odot y \). Here \( f \) is the function \( f \) \( \colon (x, y) \in K^2 \rightarrow x \odot y \).

Function `etimes_Mat`, returns element by element operation \( X \odot Y \) by using function \( f : (A, B) \mapsto A \odot B \) where \( A \) and \( B \) are in \( M_{m \times n}(K) \) or in \( K \).

Function `etimes_Vec`, returns element by element operation \( X \odot Y \) by using function \( f : (A, B) \mapsto A \odot B \) where \( A \) and \( B \) are in \( K^N \).

Function `etimes_Cvt`, returns element by element operation \( X \odot Y \) by converting arrays to a 3D-arrays. Here \( f \) is the function \( f : (A, B) \mapsto A \odot B \) where \( A \) and \( B \) are in \( (M_{m \times n}(K))^3 \).

Function `etimes_Cpt`, returns element by element product \( X \odot Y \) by using vectorized operations on 2D-arrays or matrices.

Function `etimes_Vec`, returns element by element product \( X \odot Y \) by using vectorized operations on 1D-arrays.

Function `etimes_Cvt`, returns element by element product \( X \odot Y \) by converting arrays to a 3D-arrays.

Function `etimes_Cpt`, returns matricial products \( X \odot Y \) where \( X \) or/and \( Y \) are 3D-arrays.

Function `etimes_Vec`, returns matricial products \( X \odot Y \) where \( X \) or/and \( Y \) are 3D-arrays.

Function `etimes_Mat`, returns matricial products \( X \odot Y \) where \( X \) or/and \( Y \) are 3D-arrays.

Function `linsolveDiag`, solves diagonal linear system \( AX = B \) where \( A \) is a regular lower triangular matrix.

Function `linsolveTriL _Mat`, solves equation \( AX = B \) where \( A \) is a regular lower triangular 3D-array (not vectorized).

Function `linsolveTriL_Cpt`, solves equation \( AX = B \) where \( A \) is a regular lower triangular 3D-array (not vectorized).

Function `linsolveTriL_Vec`, solves equation \( AX = B \) where \( A \) is a regular lower triangular 3D-array (vectorized).

Function `linsolveTriU`, Returns solution of equation \( AX = B \) where \( A \) is a regular upper triangular matrix.

Function `linsolveTriU_Mat`, solves equation \( AX = B \) where \( A \) is a regular upper triangular 3D-array (not vectorized).

Function `linsolveTriU_Cpt`, solves equation \( AX = B \) where \( A \) is a regular upper triangular 3D-array (not vectorized).

Function `linsolveTriU_Vec`, solves equation \( AX = B \) where \( A \) is a regular upper triangular 3D-array (vectorized).

Function `cholesky`, Computes the lower triangular matrix \( L \in M_n(C) \) such that \( B = LL^* \).

Function `cholesky_Mat`, returns cholesky factorizations of \( A_k \) matrices (not vectorized).

Function `cholesky_Cpt`, returns cholesky factorizations of \( A_k \) matrices (not vectorized).

Function `cholesky_Vec`, returns cholesky factorizations of \( A_k \) matrices (vectorized).
33 Function PALU computes the LU factorization with partial pivoting of a matrix $A$ such that $PA = LU$. 
34 Function pLUinplace inplace computation of the LU factorization with partial pivoting of a matrix $A$ such that $PA = LU$. 
35 Function PALU_MAT computes all LU factorizations with partial pivoting of a 3D-array $A$ such that $P_kA_k = L_kU_k$. 
36 Function PALU_Cpt computes all LU factorizations with partial pivoting of a 3D-array $A$ such that $P_kA_k = L_kU_k$. 
37 Function PALU_VEC computes all LU factorizations with partial pivoting of a 3D-array $A$ such that $P_kA_k = L_kU_k$. 
38 Function pLUinplace_MAT computes all LU factorizations with partial pivoting of a 3D-array $A$ such that $P_kA_k = L_kU_k$. 
39 Function pLUinplace_Cpt computes all LU factorizations with partial pivoting of a 3D-array $A$ such that $P_kA_k = L_kU_k$. 
40 Function pLUinplace_VEC computes all LU factorizations with partial pivoting of a 3D-array $A$ such that $P_kA_k = L_kU_k$. 
41 Function LinSolverCHOLESKY_VEC, solves equation $AX = B$ where $A$ is a symmetric positive definite 3D-array (vectorized) 
42 Function LinSolverPAULU_VEC, solves equation $AX = B$ where $A$ is a regular 3D-array (vectorized) 
43 Function Det_MAT, returns determinants of a 3D-array (not vectorized). 
44 Function DetLAP, returns determinant of the matrix $B$ by using Laplace formula [24] expanded with respect to the 1-st row. 
45 Function DetLAP_MAT, returns determinants of a 3D-array (not vectorized). 
46 Function DetLAP_Cpt, returns determinants of a 3D-array in $(M_d,d(K))$ (not vectorized). 
47 Function DetLAP_VEC, returns determinants of a 3D-array in $(M_d,d(K))$ (not vectorized). 
49 Function Det MIXED, returns determinant of the symmetric/Hermitian positive definite matrix $B$ by using formula [27]. 
50 Function Det MIXED_VEC, returns determinants of symmetric/Hermitian positive definite matrices $A_k$ by using formula [27] (vectorized and recursive). 
51 Function Det Vec VO4, returns determinants of the symmetric positive matrices $A_k$ by using formula [26] (vectorized, recursive and memory safe). 

List of Tables

1 Common element by element operations 
2 Computational times in seconds of $AXpbY$ functions with $X \in (M_d,d(K))$ and $Y \in M_d,d(R)$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
3 Computational times in seconds of `AXpbY_Nat` functions with
X in $(M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. Matlab(*) refers to Matlab without
multi-threadings. ......................................................... 11

4 Computational times in seconds of `AXpbY_Mat` functions with
X and Y in $(M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. Matlab(*) refers to Matlab without multi-threadings.
.............................................................................. 11

5 Function `AXpbY_Nat` with $X \in (M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ under Matlab 2018a: effects of multithreading on `cputimes` ........ 11

6 Function `AXpbY_Vec` with $X \in (M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ under Matlab 2018a: effects of multithreading on `cputimes` ........ 11

7 Function `AXpbY_Cvt` with $X \in (M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ under Matlab 2018a: effects of multithreading on `cputimes` ........ 12

8 Function `AXpbY_Mat` with $X \in (M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ under Matlab 2018a: effects of multithreading on `cputimes` ........ 12

9 Computational times in seconds of `times` functions with $X \in$
$(M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ for Matlab 2018a, Octave 4.4.0
and Python 3.6.5. ............................................................... 13

10 Computational times in seconds of `mtimes` functions with $X \in$
$(M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ for Matlab 2018a, Octave 4.4.0
and Python 3.6.5. ............................................................... 15

11 Computational times in seconds of `mtimes_Vec` functions with
X in $(M_{3,3}(K))^N$ and $Y \in M_{3,3}(R)$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. Matlab(*) refers to Matlab without
multi-threadings and Python(Nat) to Numpy `matmul` function. 15

12 Computational times in seconds of `mtimes_Vec` functions with
X and Y in $(M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. Matlab(*) refers to Matlab without multi-threadings
and Python(Nat) to Numpy `matmul` function. 15

13 Computational times in seconds of `LinsolveTriL` functions with
$A \in (M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. 20

14 Computational times in seconds of the `LinsolveTriL_Vec` function
with $A \in (M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and
Python 3.6.5. ............................................................... 20

15 Computational times in seconds of `LinsolveTriU` functions with
$A \in (M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. 23

16 Computational times in seconds of the `LinsolveTriU_Vec` function
with $A \in (M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and
Python 3.6.5. ............................................................... 23

17 Computational times in seconds of `Cholesky` functions with $A \in$
$(M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. 29

18 Computational times in seconds of the `Cholesky_Vec` function
with $A \in (M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and
Python 3.6.5. ............................................................... 29

19 Function `Cholesky_Vec` with $A \in (M_{3,3}(K))^N$ under Matlab 2018a: effect of multithreaded on `cputimes` ............... 29

20 Computational times in seconds of `PA LU` functions with $A \in$
$(M_{3,3}(K))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. 35
Computational times in seconds of PALU Vec functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Function PALU Vec with $A \in (M_{3,3}(\mathbb{K}))^N$ under Matlab 2018a: effect of multithreaded on cputimes.

Computational times in seconds of PLUinplace Vec functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Function PLUinplace Vec with $A \in (M_{3,3}(\mathbb{K}))^N$ under Matlab 2018a: effect of multithreaded on cputimes.

Computational times in seconds of pLUinplace functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Computational times in seconds of pLUinplace_Vec functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Function pLUinplace_Vec with $A \in (M_{3,3}(\mathbb{K}))^N$ under Matlab 2018a: effect of multithreaded on cputimes.

Computational times in seconds of the LinsolveCholesky_Vec function with $A \in (M_{3,3}(\mathbb{K}))^N$ and $B \in (M_{3,1}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. The last column is for the native python function numpy.linalg.solve.

Computational times in seconds of the LinsolvePALU_Vec function with $A \in (M_{3,3}(\mathbb{K}))^N$ and $B \in (M_{3,1}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Computational times in seconds of DetLap functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. The last column is for the native python function numpy.linalg.det.

Computational times in seconds of DetLap_Vec functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. The last column is for the native python function numpy.linalg.det.

Computational times in seconds of DetLapIdx functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. The last column is for the native python function numpy.linalg.det.

Computational times in seconds of DetLapIdx_Vec functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.

Computational times in seconds of DetpLUin functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5. The last column is for the native python function numpy.linalg.det.

Computational times in seconds of DetMix functions with $A \in (M_{3,3}(\mathbb{K}))^N$ for Matlab 2018a, Octave 4.4.0 and Python 3.6.5.
